“OpenGL is the premier environment for developing portable, interactive 2D and 3D graphics applications. Since its introduction in 1992, OpenGL has become the industry’s most widely used and supported 2D and 3D graphics application programming interface (API), bringing thousands of applications to a wide variety of computer platforms. OpenGL fosters innovation and speeds application development by incorporating a broad set of rendering, texture mapping, special effects, and other powerful visualization functions. Developers can leverage the power of OpenGL across all popular desktop and workstation platforms, ensuring wide application deployment.”

www.opengl.org
OpenGL: What can it do?

- Imaging part: works on pixels, bitmaps
- Geometry part: works on vertices, polygons
- uses a rendering pipeline that starts from data and ends with a display device.
OpenGL rendering pipeline
OpenGL: More info

- Application Program Interface based on C-style function calls
- industry standard: one of several (Java3D, DirectX are others)
- stable, reliable and portable
- scalable: low-end PC to supercomputer
- well documented and easy to use
OpenGL on Windows and Unix

GLU: OpenGL-Extension for complex polygons, curves etc.
The structure of an OpenGL application

```c
int main(int argc, char** argv)
{
    glutInit(&argc, argv);
    glutInitDisplayMode(GLUT_SINGLE | GLUT_RGB);
    glutInitWindowSize(640, 480);
    glutInitWindowPosition(100, 150);
    glutCreateWindow("my_first_attempt");
    glutDisplayFunc(myDisplay);
    myInit();
    glutMainLoop();
    return 0;
}
```
Other Callback Functions

```c
... glutDisplayFunc(myDisplay);
glutReshapeFunc(myReshape);
glutMouseFunc(myMouse);
glutKeyboardFunc(myKeyboard);
...
```
void myDisplay(void)
{
    glClear(GL_COLOR_BUFFER_BIT);
    glBegin(GL_POINTS);
        glVertex2i(100, 50);
        glVertex2i(100, 130);
        glVertex2i(150, 130);
    glEnd();
    glFlush();
}"
OpenGL Functions

`glVertex2i()`

- `gl` is the prefix of all OpenGL function names
- `Vertex` is a function name
- `2i` describes the arguments: two integers
OpenGL Datatypes

- `GLenum`, `GLboolean`, `GLbitfield`  
  unsigned datatypes

- `GLvoid`  
  pseudo datatype for pointers and return values

- `GLbyte`, `GLshort`, `GLint`  
  1, 2, 4-byte signed

- `GLubyte`, `GLushort`, `GLuint`  
  1, 2, 4-byte unsigned

- `GLsizei`  
  4-byte signed size datatype

- `GLsizei`  
  4-byte signed size datatype
OpenGL Datatypes

- **GLfloat**  single precision float
- **GLclampf** single precision float in [0,1]
- **GLdouble**  double precision float
- **GLclampd** double precision float in [0,1]
Drawing Dots

```c
glBegin(GL_POINTS);
    glVertex2i(100, 50);
    glVertex2i(100, 130);
    glVertex2i(150, 130);
    glVertex2i(150, 50);
glEnd();
```
Drawing a line

```cpp
glBegin(GL_LINES);
    glVertex2i(100, 50);
    glVertex2i(100, 130);
glEnd();
```
Drawing two lines

```c
begin(GL_LINES);
glVertex2i(10, 20);
glVertex2i(40, 20);
glVertex2i(20, 10);
glVertex2i(20, 40);
glEnd();
```
Drawing a polyline

```c
1 glBegin(GL_LINE_STRIP);
2 glVertex2i(10, 20);
3 glVertex2i(40, 20);
4 glVertex2i(20, 10);
5 glVertex2i(20, 40);
6 glEnd();
```
Drawing a polygon

```c
glBegin(GL_LINE_LOOP);
    glVertex2i(10, 20);
    glVertex2i(40, 20);
    glVertex2i(20, 10);
    glVertex2i(20, 40);
glEnd();
```
Drawing an aligned rectangle

```c
glRecti(x1, y1, x2, y2);
```
What are those numbers?

- There is no predefined way of interpreting the coordinates.
- OpenGL can work with different coordinate systems.
- For OpenGL, we have to define a coordinate system to be used.
void myInit(void)
{
    glClearColor(1.0, 1.0, 1.0, 0.0);
    glColor3f(0.0f, 0.0f, 0.0f);
    glPointSize(4.0);
    glMatrixMode(GL_PROJECTION);
    glLoadIdentity();
    gluOrtho2D(0.0, 640.0, 0.0, 480.0);
}
void Sierpinski(void)
{
    GLintPoint T[3]= {{10,10},{300,30},{200, 300}};
    int index = random(3);
    GLintPoint point = T[index];
    drawDot(point.x, point.y);
    for(int i = 0; i < 4000; i++) {
        index = random(3);
        point.x = (point.x + T[index].x) / 2;
        point.y = (point.y + T[index].y) / 2;
        drawDot(point.x,point.y);
    }
    glFlush();
}
Lecture 4

- Coordinate Systems, Viewports, World Windows
- Clipping
- Relative Drawing
- Parameterized Curves
- Double Buffering for Animation
Coordinate System

For now, we have used a simple coordinate system:
\[ x: 0 \ldots \text{ScreenWidth} - 1, \ y: 0 \ldots \text{ScreenHeight} - 1 \]

In case ScreenWidth or ScreenHeight change, glut can inform us via the
\[ \text{glutReshapeFunc (myReshape)}; \]

We can manually apply a coordinate transformation in order to display arbitrary coordinate systems.

Or we can have OpenGL do this for us
Some terms

- The space in which objects are described uses *world coordinates*.
- The part of this space that we want to display is called *world window*.
- The window that we see on the screen is our *viewport*.
- In order to know where to draw something, we need the *world-to-viewport transformation*.
- Note that these terms can be used both for 2D and for 3D.
A simple example

\[ sx = Ax + C \]
\[ sy = By + D \]
\[ A = \frac{V.r - V.l}{W.r - W.l} \]
\[ C = V.l - AW.l \]
\[ B = \frac{V.t - V.b}{W.t - W.b} \]
\[ D = V.b - bW.b \]
In OpenGL

```c
void setWindow(float left, float right,
               float bottom, float top)
{
    glMatrixMode(GL_PROJECTION);
    glLoadIdentity();
    gluOrtho2D(left, right, bottom, top);
}

void setViewport(int left, int right,
                 int bottom, int top)
{
    glViewport(left, bottom, right-left, top-bottom);
}
```
Clipping

- What happens to parts of the “world” that are outside of the world window?
  Answer: They are not drawn.

- How to identify the parts of the world that are to be drawn?
  
  Clipping Lines: identifying the segment of a line to be drawn

  Input: the endpoints of a line and a world window

  Output: the new endpoints of the line (if anything is to be drawn)
First step: Testing for trivial accept or reject

Cohen Sutherland Clipping Algorithm

For each point do four tests, compute 4 bit word:
1. Is P to the left of the world window?
2. Is P above the top of the world window?
3. Is P to the right of the world window?
4. Is P below the bottom of the world window?
Cohen Sutherland

- Compute tests for both points of the line
- Trivial Accept: all tests false, all bits 0
- Trivial Reject: the words for both points have 1s in the same position
- Deal with the rest: neither trivial accept nor reject
The rest

- Identify which point is outside and to which side of the window
- Find the point where the line touches the world window border
- Move the outer point to the border of the window
- repeat all until trivial accept or reject
**ClipSegment**($p_1, p_2, W$)

1: while (TRUE) do
2:   if (trivial accept) then
3:     RETURN 1
4:   end if
5:   if (trivial reject) then
6:     RETURN 0
7:   end if
8:   if (p1 is outside) then
9:     if (p1 is to the left) then
10:    chop against the left edge of W
11:   else
12:     if (p1 is to the right) then
13:      chop against the right edge of W
14:    else
15:      if ( . . . ) then
16:        ...
17:      end if
18:   end if
19: end if
20: end if
21: end while
Relative drawing

- It is often convenient to draw figures relative to a current pen position.
- Idea: maintain the current position (CP) a static global variable.
- use two functions `MOVE_REL` and `LINE_REL` to move/draw relative to CP.
- implementation is obvious. (or can be found in the book on page 105)
Application of relative drawing

- Turtle graphics: originally from the logo programming language
  - logo has been invented at MIT to teach children how to program. try google for more info

- Simple primitives: \texttt{TURNTo} (absolute angle) \texttt{TURN} (relative angle) \texttt{FORWARD} (distance, isVisible)

- Implementation obvious: maintain additional current direction (CD) in a static global variable, use simple (sin, cos) trigonometry functions for \texttt{FORWARD}. 
Application of relative drawing: n-gons

- The vertices of an n-gon lie on a circle
- divide the circle into n equal parts
- connect the endpoints of the parts on the circle with lines
- using relative drawing, this is very easy to implement
- by connecting every endpoint to every other endpoint, a rosette can be drawn
relative hexagon

```cpp
for (i=0; i<6; i++) {
    forward(L, 1);
    turn(60);
}
```
Circles and Arcs

- Circles can be approximated with n-gons (with a high $n$)
- Arcs are partially drawn circles, instead of dividing the circle, divide the arc
Representing curves

Two principle ways of describing a curve: implicitly and parametrically

Implicitly: Give a function $F$ so that $F(x, y) = 0$ for all points of the curve

Example:

$$F(x, y) = (y - A_y)(B_x - A_x) - (x - A_x)(B_y - A_y) \text{ (a line)}$$

Example: $F(x, y) = x^2 + y^2 - R^2 \text{ (a circle)}$
Implicit form of curves

- The implicit form is good for testing if a point is on a curve.

- For some cases, we can use the implicit form to define an “inside” and an “outside” of a curve:
  \[ F(x, y) < 0 \rightarrow \text{inside}, \quad F(x, y) > 0 \rightarrow \text{outside} \]

- some curves are **single valued** in \( x \): \[ F(x, y) = y - g(x) \]
  or in \( y \): \[ F(x, y) = x - h(y) \]

- some curves are neither, e.g. the circle needs two functions \( y = \sqrt{R^2 - x^2} \) and \( y = -\sqrt{R^2 - x^2} \)
Parametric form of curves

- The parametric form of a curve suggests the movement of a point through time.

- Example:
  \[ x(t) = A_x + (B_x - A_x)t, \quad y(t) = A_y + (B_y - A_y)t, \quad t \in [0, 1] \]

- Example: \( x(t) = W \cos(t), \quad y(t) = H \sin(t), \quad t \in [0, 2\pi] \)

- In order to find an implicit form from a parametric form, we can use the two \( x(t) \) and \( y(t) \) equations to eliminate \( t \) and find a relationship that holds true for all \( t \).

- For the Ellipse: \( \left( \frac{x}{W} \right)^2 + \left( \frac{y}{H} \right)^2 = 1 \)
In order to draw a parametric curve, we have to approximate it.

In order to do that, we chose some values of \( t \) and sample the functions \( x \) and \( y \) at \( t_i \).

One option is to approximate the function in between with line segments.

```plaintext
1. glBegin(GL_LINES);
2. for (i=0; i<n; i++)
3.    glVertex2f(x(t[i]),y(t[i]));
4. glEnd();
```
Superellipses

- A superellipse is defined by the implicit form
  \[(\frac{x}{W})^n + (\frac{y}{H})^n = 1\]
- A supercircle is a superellipse with \(W = H\).
- \(x(t) = W \cos(t) | \cos(t)^{2/n-1}|\)
- \(y(t) = H \sin(t) | \sin(t)^{2/n-1}|\)
Polar coordinate shapes

- Polar coordinates can be used to draw parametric curves.
- The curve is represented by a distance to the center point $r$ and an angle $\theta$.

$$x(t) = r(t) \cos(\theta(t)), y(t) = r(t) \sin(\theta(t)) \quad \text{(general form)}$$

$$x(\theta) = f(\theta) \cos(\theta), y(t) = f(\theta) \sin(\theta) \quad \text{(simple form)}$$

- Cardioid $f(\theta) = K (1 + \cos(\theta))$
- Rose Curves $f(\theta) = K \cos(n\theta)$
- Archimedian Spiral $f(\theta) = K \theta$
- Conic sections $f(\theta) = \frac{1}{1 \pm e \cos(\theta)}$
- Logarithmic Spiral $f(\theta) = K e^{a\theta}$
3D parametric curves

- We can also specify 3d curves using three functions $x(t), y(t), z(t)$
- **Helix:** $x(t) = \cos(t), y(t) = \sin(t), z(t) = bt$
- **Toroidal spiral:**
  - $x(t) = (a \sin(ct) + b) \cos(t)$
  - $y(t) = (a \sin(ct) + b) \sin(t)$
  - $z(t) = a \cos(ct)$
When we do a fast animation, the image starts to flicker.

This results from the time it takes to draw the lines.

We can avoid this via double-buffering in OpenGL, double buffering is simple:

```c
glutInitDisplayMode(GLUT_DOUBLE | GLUT_RGB);

glutSwapBuffers();
```
Lecture 5

- Vectors
- Lines and Planes in 3D space
- Affine representation
- The dot product and the cross product
- Homogenous representations
- Intersection and clipping
Vectors

- We all remember what vectors are, right?
- The difference of two points is a vector
- The sum of a point and a vector is a point
- A linear combination $a\vec{v} + b\vec{w}$ is a vector
- Let’s write $w = a_1\vec{v}_1 + a_2\vec{v}_2 + \cdots + a_n\vec{v}_n$
- If $a_1 + a_2 + \cdots + a_n = 1$ this is called an affine combination
- if additionally $a_i \geq 0$ for $i = 1\ldots n$, this is a convex combination
- To find the length of a vector, we can use Pythagoras:
  $$|\vec{w}| = \sqrt{w_1^2 + w_2^2 + \cdots + W_n^2}$$
Vectors

- When we know the length, we can normalize the vector, i.e. bring it to unit length: \( \hat{a} = \frac{\vec{a}}{|\vec{a}|} \). We can call such a unit vector a *direction*.

- The dot product of two vectors is \( \vec{a} \cdot \vec{b} = \sum_{i=1}^{n} v_i w_i \) has the well-known properties:
  - \( \vec{a} \cdot \vec{b} = \vec{b} \cdot \vec{a} \) (Symmetry)
  - \( (\vec{a} + \vec{c}) \cdot \vec{b} = \vec{a} \cdot \vec{b} + \vec{c} \cdot \vec{b} \) (Linearity)
  - \( (s\vec{a}) \cdot \vec{b} = s(\vec{a} \cdot \vec{b}) \) (Homogeneity)
  - \( |\vec{b}|^2 = \vec{b} \cdot \vec{b} \)

- We can play the usual algebraic games with vectors (simplification of equations)
Angles between vectors

We can use the dot product to find the angle between two vectors: \( \vec{a} \cdot \vec{b} = |\vec{a}| |\vec{b}| \cos(\theta) \). If the dot product of two (non-zero-length) vectors is 0 then they are perpendicular or orthogonal or normal to each other.

In 2D, we can find a perpendicular vector by exchanging the two components and negate one of them: If \( \vec{a} = (a_x, a_y) \) then \( \vec{b} = (-a_y, a_x) \) and we call this the counterclockwise perpendicular vector of \( \vec{a} \) or short \( \vec{a} \perp \).
The 2D “Perp” Vector

- The “prep” vector is useful for projections (see book, page 157)
- The distance from a point $C$ to the line through $A$ in direction $\vec{v}$ is $|\vec{v}^\perp \cdot (C - A)| / |\vec{v}|$.
- Projections are used to simulate reflections
The cross product

- Everybody remembers $\vec{a} \times \vec{b}$
- One trick to write the cross product: Let $\vec{i}, \vec{j}, \vec{k}$ be the 3D standard unit vectors. Then the cross product of $\vec{a} \times \vec{b}$ can be written as the determinant of a matrix:

$$
\vec{a} \times \vec{b} = \begin{vmatrix}
\vec{i} & \vec{j} & \vec{k} \\
a_x & a_y & a_z \\
b_x & b_y & b_z
\end{vmatrix}
$$

- and we have the usual algebraic properties: antisymmetry, linearity, homogeneity...
A coordinate system can be defined by three mutually perpendicular unit vectors.

If we put these unit vectors into a specific point \( \vartheta \) called origin, we call this a coordinate frame.

In a coordinate frame, a point can be represented as

\[ P = p_1 \vec{a} + p_2 \vec{b} + p_3 \vec{c} + \vartheta. \]

This leads to a distinction between points and vectors by using a fourth coefficient in the so-called homogenous representation of points and vectors.
Homogenous Representation

A vector in a coordinate frame:

\[ \vec{v} = (\vec{a}, \vec{b}, \vec{c}, \vec{d}) \begin{pmatrix} v_1 \\ v_2 \\ v_3 \\ 0 \end{pmatrix} \]
Homogenous Representation

A point in a coordinate frame:

\[ P = (\vec{a}, \vec{b}, \vec{c}, \vartheta) \begin{pmatrix} P_1 \\ P_2 \\ P_3 \\ 1 \end{pmatrix} \]
Homogenous coordinates

- The difference of two points is a vector
- The sum of a point and a vector is a point
- Two vectors can be added
- A vector can be scaled
- Any linear combination of vectors is a vector
- An affine combination of two points is a point. (An affine combination is a linear combination where the coefficients add up to 1.)
- A linear interpolation $P = (a(1 - t) + Bt$ is a point.
- This fact can be used to calculate a “tween” of two points.
Representing lines and planes

- A line can be represented by its endpoints $B$ and $C$
- It can also be represented parametrically with a point and a vector $L(t) = C + \mathbf{b}t$.
- A line can also be represented in point normal form $\mathbf{n} \cdot (R - C)$
- For $\mathbf{n}$ we can use $\mathbf{b} \perp$ with $\mathbf{b} = B - C$
- A plane can be represented by three points
- It can also be represented parametrically by a point and two nonparallel vectors: $P(s, t) = C + \mathbf{a}s + \mathbf{b}t$
- It can also be represented in a point normal form with a point in the plane and a normal vector. For any point $R$ in the plane $\mathbf{n} \cdot (R - B) = 0$.

A part of the plane restricted by the length of two vectors is called a planar patch.
intersections

- Every line segment has a *parent line*.
- We can first find the intersection of the parent lines and then see if the intersection point is in both line segments.
- In order to intersect a plane with a line, we describe the line parametrically and the plane in the point normal form. Solving this equation gives us a “hit time” $t$ that can be put into the parametric representation of the line to identify the *hitpoint*. 
In convex polygons, the problem is rather easy: we can test all the bounding lines/surfaces. In order to know which side of a line/plane is “outside”, we represent them in a point normal form. We have to find exactly two “hit times” $t_{in}$ and $t_{out}$. The right $t_{in}$ will be the maximal “hit time” before the ray enters the polygon. The right $t_{out}$ will be the minimal “hit time” after the ray exits the polygon. This approach can be used to clip against convex polygons. This is called the Cyrus-Beck-Clipping Algorithm.
Lecture 6

Transformations
  in 2D
  in 3D
  in OpenGL
Transformations

- Transformations are an easy way to reuse shapes.
- A transformation can also be used to present different views of the same object.
- Transformations are used in animations.
Transformations in OpenGL

- When we’re calling a `glVertex()` function, OpenGL automatically applies some transformations. One we already know is the world-window-to-viewport transformation.

- There are two principle ways do see transformations:
  - *object transformations* are applied to the coordinates of each point of an object, the coordinate system is unchanged
  - *coordinate transformations* defines a new coordinate system in terms of the old coordinate system and represents all points of the object in the new coordinate system.

- A transformation is a function that mapps a point $P$ to a point $Q$, $Q$ is called the image of $P$. 
2d affine transformations

A subset of transformations that uses transformation functions that are linear in the coordinates of the original point are the affine transformations.

We can write them as a class of linear functions:

\[
\begin{pmatrix}
Q_x \\
Q_y \\
1
\end{pmatrix}
= 
\begin{pmatrix}
m_{11} P_x + m_{12} P_y + m_{13} \\
m_{21} P_x + m_{22} P_y + m_{23} \\
1
\end{pmatrix}
\]
2d affine transformations

- or we can just use matrix multiplication

\[
\begin{pmatrix}
Q_x \\
Q_y \\
1
\end{pmatrix}
= 
\begin{pmatrix}
m_{11} & m_{12} & m_{13} \\
m_{21} & m_{22} & m_{23} \\
0 & 0 & 1
\end{pmatrix}
\begin{pmatrix}
P_x \\
P_y \\
1
\end{pmatrix}
\]

- or we can also transform vectors with the same matrix

\[
\begin{pmatrix}
W_x \\
W_y \\
0
\end{pmatrix}
= 
\begin{pmatrix}
m_{11} & m_{12} & m_{13} \\
m_{21} & m_{22} & m_{23} \\
0 & 0 & 1
\end{pmatrix}
\begin{pmatrix}
V_x \\
V_y \\
0
\end{pmatrix}
\]
standard transformations

- Translation

\[
\begin{pmatrix}
Q_x \\
Q_y \\
1
\end{pmatrix} =
\begin{pmatrix}
1 & 0 & m_{13} \\
0 & 1 & m_{23} \\
0 & 0 & 1
\end{pmatrix}
\begin{pmatrix}
P_x \\
P_y \\
1
\end{pmatrix}
\]

- Scaling (and reflection for \(S_{\{x,y\}} < 0\))

\[
\begin{pmatrix}
W_x \\
W_y \\
1
\end{pmatrix} =
\begin{pmatrix}
S_x & 0 & 0 \\
0 & S_y & 0 \\
0 & 0 & 1
\end{pmatrix}
\begin{pmatrix}
V_x \\
V_y \\
1
\end{pmatrix}
\]
standard transformations

- Rotation (positive $\theta$ is CCW rotation)

\[
\begin{bmatrix}
Q_x \\
Q_y \\
1
\end{bmatrix} = \begin{bmatrix}
\cos(\theta) & -\sin(\theta) & 0 \\
\sin(\theta) & \cos(\theta) & 0 \\
0 & 0 & 1
\end{bmatrix} \begin{bmatrix}
P_x \\
P_y \\
1
\end{bmatrix}
\]

- shearing

\[
\begin{bmatrix}
Q_x \\
Q_y \\
1
\end{bmatrix} = \begin{bmatrix}
1 & h & 0 \\
g & 1 & 0 \\
0 & 0 & 1
\end{bmatrix} \begin{bmatrix}
P_x \\
P_y \\
1
\end{bmatrix}
\]
Inverse transformations

- inverse Rotation (positive $\theta$ is CW rotation)

\[
\begin{bmatrix}
Q_x \\
Q_y \\
1
\end{bmatrix} = \begin{bmatrix}
\cos(\theta) & \sin(\theta) & 0 \\
-\sin(\theta) & \cos(\theta) & 0 \\
0 & 0 & 1
\end{bmatrix} \begin{bmatrix}
P_x \\
P_y \\
1
\end{bmatrix}
\]

- inverse Scaling

\[
\begin{bmatrix}
Q_x \\
Q_y \\
1
\end{bmatrix} = \begin{bmatrix}
\frac{1}{S_x} & 0 & 0 \\
0 & \frac{1}{S_y} & 0 \\
0 & 0 & 1
\end{bmatrix} \begin{bmatrix}
P_x \\
P_y \\
1
\end{bmatrix}
\]
Inverse transformations

- **inverse shearing**

\[
\begin{pmatrix}
Q_x \\
Q_y \\
1
\end{pmatrix}
= \begin{pmatrix}
1 & -h & 0 \\
-g & 1 & 0 \\
0 & 0 & 1
\end{pmatrix}
\begin{pmatrix}
P_x \\
P_y \\
1
\end{pmatrix}
\]

- **inverse translation**

\[
\begin{pmatrix}
Q_x \\
Q_y \\
1
\end{pmatrix}
= \begin{pmatrix}
1 & 0 & -m_{13} \\
0 & 1 & -m_{23} \\
0 & 0 & 1
\end{pmatrix}
\begin{pmatrix}
P_x \\
P_y \\
1
\end{pmatrix}
\]
In general (provided that $M$ is nonsingular)

$$P = M^{-1}Q$$

But as $M$ is quite simple:

$$\det M = m_{11}m_{22} - m_{12}m_{21}$$

$$M^{-1} = \frac{1}{\det M} \begin{pmatrix} m_{22} & -m_{12} \\ -m_{21} & m_{11} \end{pmatrix}$$
composing affine transformations

- As affine transformations are simple matrix multiplications, we can combine several operations to a single matrix.
- In a matrix multiplication of transformations, the sequence of translations can be read from right to left.
- We can also take this combined matrix and reconstruct the four basic operations  
  \[ M = (\text{translation})(\text{shear})(\text{scaling})(\text{rotation}) \]  
  (this is for 2D only)
Some more facts

- Affine transformations preserve affine combinations of points
- Affine transformations preserve lines and planes
- Affine transformations preserve parallelism of lines and planes
- The column vectors of an affine transformation reveal the effect of the transformation on the coordinate system.
- An affine transformation has an interesting effect on the area of an object:

\[
\frac{\text{area after transformation}}{\text{area before transformation}} = | \det M |
\]
The same game in 3D...

The general form of an affine 3D transformation

\[
\begin{pmatrix}
Q_x \\
Q_y \\
Q_z \\
1
\end{pmatrix} =
\begin{pmatrix}
m_{11} & m_{12} & m_{13} & m_{14} \\
m_{21} & m_{22} & m_{23} & m_{24} \\
m_{31} & m_{32} & m_{33} & m_{34} \\
0 & 0 & 0 & 1
\end{pmatrix}
\begin{pmatrix}
P_x \\
P_y \\
P_z \\
1
\end{pmatrix}
\]
As expected:

\[
\begin{pmatrix}
Q_x \\
Q_y \\
Q_z \\
1
\end{pmatrix} =
\begin{pmatrix}
1 & 0 & 0 & m_{14} \\
0 & 1 & 0 & m_{24} \\
0 & 0 & 1 & m_{34} \\
0 & 0 & 0 & 1
\end{pmatrix}
\begin{pmatrix}
P_x \\
P_y \\
P_z \\
1
\end{pmatrix}
\]
Scaling in 3D...

Again:

\[
\begin{pmatrix}
Q_x \\
Q_y \\
Q_z \\
1
\end{pmatrix}
= 
\begin{pmatrix}
S_x & 0 & 0 & 0 \\
0 & S_y & 0 & 0 \\
0 & 0 & S_z & 0 \\
0 & 0 & 0 & 1
\end{pmatrix}
\begin{pmatrix}
P_x \\
P_y \\
P_z \\
1
\end{pmatrix}
\]
Shearing... in one direction

\[
\begin{pmatrix}
Q_x \\
Q_y \\
Q_z \\
1
\end{pmatrix}
= \begin{pmatrix}
1 & 0 & 0 & 0 \\
f & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{pmatrix}
\begin{pmatrix}
P_x \\
P_y \\
P_z \\
1
\end{pmatrix}
\]
Rotations 3D...

- x-roll, y-roll and z-roll
- x-roll:

\[
\begin{pmatrix}
Q_x \\
Q_y \\
Q_z \\
1
\end{pmatrix} =
\begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & c & -s & 0 \\
1 & s & c & 0 \\
0 & 0 & 0 & 1
\end{pmatrix}
\begin{pmatrix}
P_x \\
P_y \\
P_z \\
1
\end{pmatrix}
\]
Rotations 3D...

y-roll:

\[
\begin{pmatrix}
Q_x \\
Q_y \\
Q_z \\
1
\end{pmatrix}
= \begin{pmatrix}
c & 0 & s & 0 \\
0 & 1 & 0 & 0 \\
-s & 0 & c & 0 \\
0 & 0 & 0 & 1
\end{pmatrix}
\begin{pmatrix}
P_x \\
P_y \\
P_z \\
1
\end{pmatrix}
\]
Rotations 3D...

- z-roll:

\[
\begin{pmatrix}
Q_x \\
Q_y \\
Q_z \\
1
\end{pmatrix}
= \begin{pmatrix}
c & -s & 0 & 0 \\
s & c & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{pmatrix}
\begin{pmatrix}
P_x \\
P_y \\
P_z \\
1
\end{pmatrix}
\]
Some facts about Rotations 3D

- 3D affine transformations can be composed as in 2D.
- 3D rotation matrices do not commute (unlike 2D).
- Question: how to rotate around an arbitrary axis?
- Every 3D affine transformation can be decomposed into (translation)(scaling)(rotation)(shear$_1$)(shear$_2$).
- A 3D affine transformation has an effect on the volume of an object: \[
\frac{\text{volume after transformation}}{\text{volume before transformation}} = | \det M |
\]
point vs coordinate system transformations

If we have an affine transformation $M$, we can use it to transform a coordinate frame $F_1$ into a coordinate frame $F_2$.

A point $P = (P_x, P_y, 1)^T$ represented in $F_2$ can be represented in $F_1$ as $MP$.

$F_1 \rightarrow M_1 F_2 \rightarrow M_2 F_3$ then $P$ in $F_3$ is $M_1 M_2 P$ in $F_1$.

To apply the sequence of transformations $M_1, M_2, M_3$ to a point $P$, calculate $Q = M_3 M_2 M_1 P$. An additional transformation must be premultiplied.

To apply the sequence of transformations $M_1, M_2, M_3$ to a coordinate system, calculate $M = M_1 M_2 M_3$. A point $P$ in the transformed coordinate system has the coordinates $MP$ in the original coordinate system. An additional transformation must be postmultiplied.
And now in OpenGL...

- Of course we can do everything by hand: build a point and vector datatype, implement matrix multiplication, apply transformations and call `glVertex` in the end.

- In order to avoid this, OpenGL maintains a *current transformation* that is applied to every `glVertex` command. This is independent of the window-to-viewport translation that is happening as well.

- The current transformation is maintained in the *modelview matrix*.
And now in OpenGL...

- It is initialized by calling `glLoadIdentity`
- The modelview matrix can be altered by `glScaled()`, `glRotated` and `glTranslated`.
- These functions can alter any matrix that OpenGL is using. Therefore, we need to tell OpenGL which matrix to modify: `glMatrixMode(GL_MODELVIEW)`.
The 2D transformations

Scaling in 2d:

```cpp
1. glMatrixMode(GL_MODELVIEW);
2. glScaled(sx, sy, 1.0);
```

Translation in 2d:

```cpp
1. glMatrixMode(GL_MODELVIEW);
2. glTranslated(dx, dy, 0);
```

Rotation in 2d:

```cpp
1. glMatrixMode(GL_MODELVIEW);
2. glRotated(angle, 0.0, 0.0, 1.0);
```
A stack of CTs

- Often, we need to “go back” to a previous CT. Therefore, OpenGL maintains a “stack” of CTs (and of any matrix if we want to).
- We can push the current CT on the stack, saving it for later use: `glPushMatrix()`. This pushes the current CT matrix and makes a copy that we will modify now.
- We can get the top matrix back: `glPopMatrix()`.
3D! (finally)

For our 2D cases, we have been using a very simple parallel projection that basically ignores the perspective effect of the $z$-component.

The view volume forms a rectangular parallelepiped that is formed by the border of the window and the near plane and the far plane.

Everything in the view volume is parallel-projected to the window and displayed in the viewport. Everything else is clipped off.

We continue to use the parallel projection, but make use of the $z$ component to display 3D objects.
3D Pipeline

- The 3d Pipeline uses three matrix transformations to display objects
  - The modelview matrix
  - The projection matrix
  - The viewport matrix
- The modelview matrix can be seen as a composition of two matrices: a model matrix and a view matrix.
Set up the projection matrix and the viewing volume:

\[
\text{glMatrixMode(GL_PROJECTION);} ;
\text{glLoadIdentity();}
\text{glOrtho(left, right, bottom, top, near, far);}
\]

Aiming the camera. Put it at eye, look at look and upwards is up.

\[
\text{glMatrixMode(GL_MODELVIEW);} ;
\text{glLoadIdentity();}
\text{gluLookAt(eye_x, eye_y, eye_z, look_x, look_y, look_z, up_x, up_y, up_z);}
\]
Basic shapes in OpenGL

- A wireframe cube:
  
  ```
  glutWireCube(GLdouble size);
  ```

- A wireframe sphere:
  
  ```
  glutWireSphere(GLdouble radius,
  GLint nSlices,GLint nStacks);
  ```

- A wireframe torus:
  
  ```
  glutWireTorus(GLdouble inRad, GLdouble outRad,
  GLint nSlices,GLint nStacks);
  ```
And the most famous one...

- How was it again with those coordinates?
- representing hierarchic object structures
- perspective
Again: And now in OpenGL...

- Of course we can do everything by hand: build a point and vector datatype, implement matrix multiplication, apply transformations and call `glVertex` in the end.

- In order to avoid this, OpenGL maintains a *current transformation* that is applied to every `glVertex` command. This is independent of the window-to-viewport translation that is happening as well.

- The current transformation is maintained in the *modelview matrix*. 
Again: And now in OpenGL...

- It is initialized by calling `glLoadIdentity`
- The modelview matrix can be altered by `glScaled()` , `glRotated` and `glTranslated`.
- These functions can alter any matrix that OpenGL is using. Therefore, we need to tell OpenGL which matrix to modify: `glMatrixMode(GL_MODELVIEW)`.
Again: A stack of CTs

- Often, we need to “go back” to a previous CT. Therefore, OpenGL maintains a “stack” of CTs (and of any matrix if we want to).
- We can push the current CT on the stack, saving it for later use: `glPushMatrix()`. This pushes the current CT matrix and makes a copy that we will modify now.
- We can get the top matrix back: `glPopMatrix()`.
Again: 3D

For our 2D cases, we have been using a very simple parallel projection that basically ignores the perspective effect of the $z$-component.

the view volume forms a rectangular parallelepiped that is formed by the border of the window and the near plane and the far plane.

everything in the view volume is parallel-projected to the window and displayed in the viewport. Everything else is clipped off.

We continue to use the parallel projection, but make use of the $z$ component to display 3D objects.
Again: 3D Pipeline

- The 3d Pipeline uses three matrix transformations to display objects:
  - The modelview matrix
  - The projection matrix
  - The viewport matrix

- The modelview matrix can be seen as a composition of two matrices: a model matrix and a view matrix.
Again: in OpenGL

Set up the projection matrix and the viewing volume:

```
1. glMatrixMode(GL_PROJECTION);
2. glLoadIdentity();
3. glOrtho(left, right, bottom, top, near, far);
```

Aiming the camera. Put it at eye, look at look and upwards is up.

```
1. glMatrixMode(GL_MODELVIEW);
2. glLoadIdentity();
3. gluLookAt(eye_x, eye_y, eye_z, look_x, look_y, look_z, up_x, up_y, up_z);
```
Basic shapes in OpenGL

- A wireframe cube:
  ```c
  glutWireCube(GLdouble size);
  ```

- A wireframe sphere:
  ```c
  glutWireSphere(GLdouble radius,
                 GLint nSlices, GLint nStacks);
  ```

- A wireframe torus:
  ```c
  glutWireTorus(GLdouble inRad, GLdouble outRad,
                GLint nSlices, GLint nStacks);
  ```
And the most famous one...

- The Teapot

```c
glutWireTeapot(GLdouble size);
```
The five Platonic solids

- **Tetrahedron**: `glutWireTetrahedron()`
- **Octahedron**: `glutWireOctahedron()`
- **Dodecahedron**: `glutWireDodecahedron()`
- **Icosahedron**: `glutWireIcosahedron()`

Missing one?
Moving things around

- All objects are drawn at the origin.
- To move things around, use the following approach:

```c
1. glMatrixMode(GL_MODELVIEW);
2. glPushMatrix();
3. glTranslated(0.5,0.5,0.5);
4. glutWireCube(1.0);
5. glPopMatrix();
```
Rotating things

To rotate things, use the following approach:

```c
1. glMatrixMode(GL_MODELVIEW);
2. glPushMatrix();
3. glRotatef(angle, 0.0, 1.0, 0.0);
4. glutWireTeapot(1.0);
5. glPopMatrix();
```
Hierarchical Modeling

- If we try to model an everyday object (like a house), we do not want to move all its components separately.
- Instead we want to make sure that if we move the house, the roof of the house move together with the walls.
- The CT stack gives us a simple way to implement this.
Global motion

The easiest case of hierarchical modeling is global motion.

To implement it, we apply a number of transforms before we start drawing objects.

```c
1 glMatrixMode(GL_MODELVIEW);
2 glPushMatrix();
3 glTranslated(x, y, z);
4 glRotatef(turnit, 0.0, 1.0, 0.0);
5 drawMyScene();
6 glPopMatrix();
```
Local motion

To implement local motion, apply an extra transformation before the object is drawn

```c
drawmyteapot()
{
    glMatrixMode(GL_MODELVIEW);
    glPushMatrix();
    glRotatef(spinit, 0.0, 0.0, 1.0);
    glutWireTeapot(1.0);
    glPopMatrix();
}
```
Perspective

- Our current parallel projection is quite poor in giving us a "real" view of things.
- That is because it is "ignoring" the z component which leads to ambiguities.
from http://www.leinroden.de/
Perspective in OpenGL

Set up the projection matrix and the viewing volume:

```c
1. glMatrixMode(GL_PROJECTION);
2. glLoadIdentity();
3. gluPerspective(viewAngle, aspectRatio, N, F);
```

Aiming the camera. Put it at eye, look at look and upwards is up. (no change here)

```c
1. glMatrixMode(GL_MODELVIEW);
2. glLoadIdentity();
3. gluLookAt(eye_x, eye_y, eye_z,
4.   look_x, look_y, look_z, up_x, up_y, up_z);
```
Perspective

The point perspective in OpenGL resolves some ambiguities
but it cannot solve all ambiguities
Perspective

Lecture 8

- Solid Modeling
- Polygonal Meshes
- Shading
Solid Modeling

- We can model a solid object as a collection of polygonal faces.
- Each face can be specified as a number of vertices and a normal vector (to define the inside and the outside).
- For clipping and shading, it is useful to associate a normal vector with every vertex. Multiple vertices can be associated with the same normal vector and a vertex can be associated with multiple normal vectors.
- To represent an object, we could store all vertices for all polygons together with a normal vector for every vertex. That would be highly redundant.
Storing polygonal meshes

Instead, we can use three lists:
- the vertex list
  It contains all distinct vertices
- the normal list
  It contains all distinct normal vectors
- the face list
  It only contains lists of indices of the two other lists
The basic barn

Finding the normal vectors

- We can compute the normal of a face using three vectors and the cross product
  \[ m = (V_1 - V_2) \times (V_3 - V_2) \] and normalize it to unit length.

- Two problems arise:
  - What if \((V_1 - V_2)\) and \((V_3 - V_2)\) are almost parallel?
  - What to do with faces that are defined through more than three vertices?

- Instead, we can use Newell’s method:
  \[
  \begin{align*}
  m_x &= \sum_{i=0}^{N-1} (y_i - y_{\text{next}(i)}) (z_i + z_{\text{next}(i)}) \\
  m_y &= \sum_{i=0}^{N-1} (z_i - z_{\text{next}(i)}) (x_i + x_{\text{next}(i)}) \\
  m_z &= \sum_{i=0}^{N-1} (x_i - x_{\text{next}(i)}) (y_i + y_{\text{next}(i)})
  \end{align*}
  \]
Properties of polygonal meshes

- Solidity (if the faces enclose a positive and finite amount of space)
- Connectedness (if there is a path between every two vertices along the polygon edges)
- Simplicity (if the object is solid and has no “holes”)
- Planarity (if every face is planar, i.e. every vertex of a polygon lies in a plane)
- Convexity (if a line connecting any two points in the object lies completely within the object)
- A Polyhedron is a connected mesh of simple planar polygons that encloses a finite amount of space
Properties of polyhedrons

- Every edge is shared by exactly two faces
- At least three edges meet at each vertex
- Faces do not interpenetrate: they either touch at a common edge or not at all.
- Euler’s formula for simple polyhedrons: \( V + F - E = 2 \)
  (E: Edges, F: Faces, V: Vertices)
- For non-simple polyhedrons: \( V + F - E = 2 + H - 2G \)
  (G: holes in the polyhedron, H: holes in faces)
Lecture 9

Shading
- Toy physics and shading models
- diffuse reflection
- specular reflections
- and everything in OpenGL
Shading

- Displaying Wireframe models is easy from a computational viewpoint
- But it creates lots of ambiguities that even perspective projection cannot remove
- If we model objects as solids, we would like them to look “normal”. One way to produce such a normal view is to simulate the physical processes that influence their appearance (Ray Tracing). This is computationally very expensive.
- We need a cheaper way that gives us some realism but is easy to compute. This is shading.
Types of shading

- Remove hidden lines in wireframe models
- Flat Shading
- Smooth Shading
- Adding specular light
- Adding shadows
- Adding texture
Toy-Physics for CG

- There are two types of light sources: ambient light and point light sources.
- If all incident light is absorbed by a body, it only radiates with the so-called blackbody radiation that is only dependent of its temperature. We’re dealing with cold bodys here, so blackbody radiation is ignored.
- Diffuse Scattering occurs if light penetrates the surface of a body and is then re-radiated uniformly in all directions. Scattered lights interact strongly with the surface, so it is usually colored.
- Specular reflections occur in metal- or plastic-like surfaces. These are mirrorlike and highly directional.
- A typical surface displays a combination of both effects.
Important vector tools for shading

- The normal vector $\vec{m}$ to the surface $P$.
- The vector $\vec{v}$ from $P$ to the viewer’s eye.
- The vector $\vec{s}$ from $P$ to the light source.
- The cosine of two vectors is the normalized dot-product.

$$\frac{\vec{a} \cdot \vec{b}}{|\vec{a}||\vec{b}|}$$
Calculating the diffuse component $I_d$

- Diffuse scattering is uniform, so forget $v$ (unless we do not see the surface, $v \cdot m < 0$)
- It depends on $s$ vs. $m$.
- Lambert’s Law: A surface receives the illumination from a light source that is proportional to the cosine of the angle between the normal of the surface and the direction to the light source.

$$I_d = I_s \rho_d \frac{s \cdot m}{|s||m|}$$

- $I_d$ is the intensity of the light source, $\rho_d$ is the diffuse reflection coefficient.
- We do not want negative intensities, so we set negative values of the cosine term to zero.
Specular reflection

- The specular reflection component is $I_d$.
- Specular reflection is not uniform, so it should depend on $\vec{s}, \vec{m}$ and $\vec{v}$.
- Several models have been developed for modeling specular reflection, the one OpenGL uses is the model by Phong (1975, Communications of the ACM 18: Illumination for Computer Generated Images).
- Phong: The light reflected in the direct mirror direction is the strongest. Light reflected in other directions is proportional to the $f$ th power of the cosine to the mirror direction.
Specular reflection (2)

- The mirror direction \( \vec{r} \) can be found like this:
  \[
  \vec{r} = -\vec{s} + 2\frac{(\vec{s} \cdot \vec{m})}{|\vec{m}|^2} \vec{m}
  \]

- \( I_{sp} = I_s \rho_s \left( \frac{\vec{r}}{|\vec{r}|} \cdot \frac{\vec{v}}{|\vec{v}|} \right)^f \)

- Again, \( I_d \) is the intensity of the light source, \( \rho_{sp} \) is the specular reflection coefficient. \( f \) is determined experimentally and lies between 1 and 200.

- Finding \( \vec{r} \) is computationally expensive.
Avoid finding $\vec{r}$

- Instead of finding the correct $\vec{r}$, compute the *halfway vector* between $\vec{s}$ and $\vec{v}$: $\vec{h} = \vec{s} + \vec{v}$.

- $\vec{h}$ gives the direction in which the brightest light is to be expected if all vectors are in the same plane.

- $I_{sp} = I_s \rho_s \left( \frac{\vec{h}}{|\vec{h}|} \cdot \frac{\vec{m}}{|\vec{m}|} \right)^f$

- The falloff of the cosine function is now a different one. But this can be compensated by choosing a different $f$.

- Of course all these models are not very realistic, but easy to compute.
Ambient Light

- Ambient light is a uniform background light that exists everywhere in the scene. It models the light that is usually reflected from surfaces.

- Its source has an intensity $I_a$. Every surface has an ambient reflection coefficient $\rho_a$ (often equal to $\rho_d$).

- All light contributions combined:

$$I = I_a \rho_a + I_d \rho_d \times \text{lambert} + I_{sp} \rho_s \times \text{phong}^f$$
Color Light

It’s easy to extend this model to colored light: Simply treat the three color components separately:

\[
I_r = I_{ar}\rho_{ar} + I_{dr}\rho_{dr} \times \text{lambert} + I_{spr}\rho_{sr} \times \text{phong}^f
\]
\[
I_g = I_{ag}\rho_{ag} + I_{dg}\rho_{dg} \times \text{lambert} + I_{spg}\rho_{sg} \times \text{phong}^f
\]
\[
I_b = I_{ab}\rho_{ab} + I_{db}\rho_{db} \times \text{lambert} + I_{spb}\rho_{sb} \times \text{phong}^f
\]
In OpenGL

Creating a light source:

```c
GLfloat myLightPosition[] = {3.0, 6.0, 5.0, 1.0};
glLightfv(GL_LIGHT0, GL_POSITION, myLightPosition);
glEnable(GL_LIGHTING);
glEnable(GL_LIGHT0);
```

OpenGL handles up to 8 light sources **LIGHT0** to **LIGHT7**.

Giving a vector instead of a position creates a light source of infinite distance. This type of light source is called *directional* instead of *positional*. 
Colored Light

Creating a light source:

```c
GLfloat amb0[] = {0.2, 0.4, 0.6, 1.0};
GLfloat diff0[] = {0.8, 0.9, 0.5, 1.0};
GLfloat spec0[] = {1.0, 0.8, 1.0, 1.0};
glLightfv(GL_LIGHT0, GL_AMBIENT, amb0);
glLightfv(GL_LIGHT0, GL_DIFFUSE, diff0);
glLightfv(GL_LIGHT0, GL_SPECULAR, spec0);
```

Colors are specified in the RGBA model. A stands for *alpha*. For the moment, we set alpha to 1.0.
By default, OpenGL uses point light sources.

Creating a spot light source:

```c
1. glLightf(GL_LIGHT0, GL_SPOT_CUTOFF, 45.0);
2. glLightfv(GL_LIGHT0, GL_SPOT_EXPONENT, 4.0);
3. GLfloat dir[] = {2.0, 1.0, -4.0};
4. glLightfv(GL_LIGHT0, GL_SPOT_DIRECTION, dir);
```
Other light properties

- **Light attenuation:**

```c
1. glLightf(GL_LIGHT0, GL_CONSTANT_ATTENUATION, 2.0);
2. glLightf(GL_LIGHT0, GL_LINEAR_ATTENUATION, 0.2);
3. glLightf(GL_LIGHT0, GL_QUADRATIC_ATTENUATION, 0.1);
```

- **Ambient Light:**

```c
1. GLfloat amb[] = {0.2, 0.3, 0.1, 1.0};
2. glLightModelfv(GL_LIGHT_MODEL_AMBIENT, amb);
```
Other light properties

- Recompute $\vec{v}$ for every point

```c
void glLightModeli(
    GL_LIGHT_MODEL_LOCAL_VIEWER,
    GL_TRUE);
```

- Faces are two-sided:

```c
void glLightModeli(
    GL_LIGHT_MODEL_TWO_SIDE,
    GL_TRUE);
```
Material properties

Set the diffuse component for a surface:

```
1. GLfloat myDiffuse[]={0.8,0.2,0.0,1.0};
2. glMaterialfv(GL_FRONT,GL_DIFFUSE,myDiffuse);
```

- The first parameter chooses the face: GL_FRONT, GL_BACK, GL_FRONT_AND_BACK
- The second parameter chooses the coefficients: GL_AMBIENT, GL_DIFFUSE, GL_SPECULAR, GL_AMBIENT_AND_DIFFUSE, GL_EMISSION
Lab Session tomorrow

- Set up a scene
- Define some materials
- Set up some lights
- Play around
Lecture 10

- Smooth objects
  - Representation
  - Generic Shapes
- Flat vs. Smooth Shading
- Perspective and (pseudo) Depth
Smooth Objects

Remember the n-gon?

```plaintext
for (i=0; i<N; i++)
{
    forward(L, 1);
    turn(360/N);
}
```
Mesh approximations

- Smooth objects can be approximated with fine meshes.
- For shading, we want to preserve the information that these objects are actually smooth so that we can shade them "round".
- The basic approach: Use a parametric representation of the object and "polygonalize" it. (also called "tesselation")
Lecture 4: Representing Curves

Two principle ways of describing a curve: implicitly and parametrically

Implicitly: Give a function $F$ so that $F(x, y) = 0$ for all points of the curve

The parametric form of a curve suggests the movement of a point through time.

Lecture 5: Representing a planar patch:

$P(s, t) = C + \vec{a}s + \vec{b}t, s, t \in [0, 1]$
Representing surfaces

- Parametric form: \( P(u, v) = (X(u, v), Y(u, v), Z(u, v)) \)
- Keeping \( v \) fixed and let \( u \) vary: \( v \)-contour
- Keeping \( u \) fixed and let \( u \) vary: \( u \)-contour
- Implicit form: \( F(x, y, z) = 0 \)
- \( F \) is also called the inside-outside-function:
  \[ F < 0 : \text{inside}, \quad F = 0 \text{ on the surface}, \quad F > 0 \text{ outside.} \]
Normal vectors of parametric surfaces

\[ \vec{p}(u, v) \] is the vector from the origin of the surface to \( P(u, v) \).

\[ \vec{n}(u_0, v_0) \] is the normal vector in surface point \( P(u_0, v_0) \).

\[ \vec{n}(u_0, v_0) = \left( \frac{\partial \vec{p}}{\partial u} \times \frac{\partial \vec{p}}{\partial v} \right) \bigg|_{u=u_0, v=v_0} \]
Normal vectors of parametric surfaces

As \( p(u, v) = X(u, v)\mathbf{i} + Y(u, v)\mathbf{j} + Z(u, v)\mathbf{k} \):

\[
\frac{\partial p(u, v)}{\partial u} = \left( \frac{\partial X(u, v)}{\partial u}, \frac{\partial Y(u, v)}{\partial u}, \frac{\partial Z(u, v)}{\partial u} \right)
\]
Normal vectors of implicit surfaces

We can use the gradient $\nabla F$ of the surface as the normal vector:

$$\vec{n}(x_0, y_0, z_0) = \nabla F \bigg|_{x=x_0, y=y_0, z=z_0}$$

$$= \left( \frac{\partial F}{\partial x}, \frac{\partial F}{\partial y}, \frac{\partial F}{\partial z} \right) \bigg|_{x=x_0, y=y_0, z=z_0}$$
Affine Transformations

We can apply affine transformation to the homogenous form of the representations: if
\[ \tilde{P}(u, v) = (X(u, v), Y(u, v), Z(u, v), 1)^T, \] then \[ M\tilde{P}(u, v) \]
is the parametric representation under the transformation \( M \).

We can apply a transformation to the implicit form
\[ F(\tilde{P}): F'(\tilde{P}) = F(M^{-1}\tilde{P}) \]

The normal vector of the transformed surface is
\[ M^{-T}\tilde{n}(u, v) \]
Some generic shapes

**Sphere:**
\[ F(x, y, z) = x^2 + y^2 + z^2 - 1 \]
\[ P(u, v) = (\cos(v) \cos(u), \cos(v) \sin(u), \sin(v)) \]

u-contours are called *meridians*, v-contours are called *parallels*

**Tapered Cylinder:**
\[ F(x, y, z) = x^2 + y^2 - (1 + (s - 1)z)^2 \text{ for } 0 < z < 1 \]
\[ P(u, v) = ((1+(s-1)v) \cos(u), (1+(s-1)v) \sin(u), v) \]
\[ s = 1: \text{ Cylinder, } s = 0: \text{ Cone} \]
Shading

- Flat shading: Compute the color for each face, fill the entire face with the color.
- Flat shading is OK if light sources are far away.
- Flat shading especially looks bad on approximated smooth objects.

```c
in OpenGL: glShadeModel(GL_FLAT);
```
Smooth Shading

Gouraud Shading: Compute a different color for every pixel.

For each scanline at $y_s$ compute $color_{left}$ by linear interpolation between the color of the top and bottom of the left edge.

Compute $color_{right}$ the same way.

Then fill the scanline by linear interpolation between $color_{left}$ and $color_{right}$.

in OpenGL: `glShadeModel(GL_SMOOTH);`
Better Smooth Shading

- Phong Shading: Compute a different normal vector for every pixel.
- Instead of interpolating the colors, interpolate the normal vectors
- in OpenGL: not implemented
Removing hidden surfaces

- Depth Buffer: Stores a value for every pixel
- During shading: For each pixel compute a pseudodepth.
- Only draw the pixel if its pseudodepth is lower, and update the pseudodepth if the pixel is drawn.
- Again, compute the correct pseudodepth for the endpoints of the scanline and use interpolation in between.
Lecture 11

Insert Demos Here
Removing hidden surfaces

- Depth Buffer: Stores a value for every pixel
- During shading: For each pixel compute a pseudodepth.
- Only draw the pixel if its pseudodepth is lower, and update the pseudodepth if the pixel is drawn.
- Again, compute the correct pseudodepth for the endpoints of the scanline and use interpolation in between.
What is pseudodepth?

- A perspective projection projects a 3D point to a 2D point.
- The parallel projection is the most simple one. It removes the z-Component.
- A better perspective projection is the following:

\[
(x^*, y^*) = \left( N \frac{P_x}{-P_z}, N \frac{P_y}{-P_z} \right)
\]

N is the distance from the eye to the near plane.
What is pseudodepth?

- Pseudodepth should be lower if a point is in front of another point.
- Unfortunately, the projection removes this information.
- We could use $P_z$ directly.
- But it’s more convenient to set the pseudodepth to a fixed interval, i.e. $-1 \ldots 1$.
- And it’s convenient to use the same denominator $-P_z$. 
What is pseudodepth?

So we can use:

\[(x^*, y^*, z^*) = \left( N\frac{P_x}{P_z}, N\frac{P_y}{P_z} \frac{aP_z + b}{-P_z} \right)\]

for the right \(a\) and \(b\).
Pseudodepth in a projection matrix

This projection matrix computes the pseudodepth and the perspective projection at the same time:

\[
P = \begin{pmatrix}
N & 0 & 0 & 0 \\
0 & N & 0 & 0 \\
0 & 0 & a & b \\
0 & 0 & -1 & 0
\end{pmatrix}
\]
Lecture 12

- Pixmaps
- Colors
- Texture
Pixmaps

- From Lecture 2: A Pixel is a point sample and a pixmap (or pixel map or “bitmap”) is created by sampling an original discrete points. In order to restore an image from pixels, we have to apply a reconstruction filter.

- Reconstruction filters are e.g. Box, Linear, Cubic, Gaussian...

- OpenGL is another method to create these point samples: for every pixel in the viewport window, OpenGL determines its color value.
Pixmaps

- Internally, OpenGL stores these pixmaps in *buffers*.
- The call to `glutInitDisplayMode()` allocates the basic draw buffer(s).

Colors

- Visible light is a continuum, so there is no “natural” way to represent color.

- RGB color model
  - Inspired by human perception
  - Three spectral components: red, green, blue
  - Binary representation of the component values, different standards
  - Example: 16-bit RGB (565): one short, 5 bits for red and blue, 6 bits for green.
RGB in CIE Cromaticity Diagram

This figure includes all the colors perceivable by the normal human eye.
Colors

- Y/Cr/Cb
- based on the CIE Cromaticity Diagram
- used for TV applications: compatible with old B/W TV standards
- Y: greyscale component, Cr: red-green-component, Cb: blue-green-component
- possibility to reduce bandwidth for color “signal”
Colors

- **HSI model**
  - hue: color (i.e. dominant wavelength), saturation: ratio between white and color, intensity: ratio between black and color
  - good for computer vision applications
Colors

- CYM(K) model
  - subtractive color model: white light is filtered, spectral components are removed.
  - C: cyan (removes red) Y: yellow (removes blue) M: magenta (removes green)
  - K: coal (i.e. black) removes everything.
  - often used in print production
Colors

Conversion between different color models (and output devices) often leads to different colors. In order to get the “right” color, the devices have to be color-corrected. This is the task of a color management system.
Never The Same Color

In pixmaps, colors are represented using binary values. This leads to problems:
- quantization errors: when using few bits per pixel
- minimum and maximum values: clamping

But other things go wrong too.
Display devices react nonlinearily: A intensity value of 128 is less than half as bright than 255.
Gamma correction

The intensity of the display devices is roughly a power function:

\[ i_D \approx \left( \frac{i}{255} \right)^\gamma \]

\( \gamma \) is usually in the range of 1.7 \ldots 2.5.
Different gamma values
What's the gamma?

(from http://www.graphics.cornell.edu/westin/gamma.html)
What’s the A in RGBA?

- OpenGL represents pixmaps internally using 4 values per pixel, RGB and A.
- The A stands for $\alpha$, i.e. Alpha and indicates the transparent regions of a pixmap.
- $\alpha$ is a measure of opacity, $(1 - \alpha)$ is transparency
  - $\alpha = 1$ Pixel is fully opaque
  - $\alpha = 0$ Pixel is fully transparent
  - $0 < \alpha < 1$ Pixel is semi transparent
Compositing

The alpha values of a pixmap are called the alpha matte of the pixmap.

The process of merging two images with alpha mattes is called compositing or alpha blending.

Given two pixels $F$ (foreground) and $B$ (background) and $\alpha$ for the foreground pixel.

$B_{\text{new}} = (1 - \alpha)B_{\text{old}} + \alpha F$

$B_{\text{new}} = B_{\text{old}} + \alpha(F - B_{\text{old}})$

OpenGL uses this in its blending functions.
Associated Color

- Treating alpha and colors separately gives strange effects when filtering or interpolating.

- But storing the pixels already premultiplied with their opacity removes the effect. This is called associated color or opacity-weighted color.

*Figure 8. Left: Artifacts of separate interpolation of colors and opacity. Right: Improved using opacity-weighted color interpolation.*
Associated Color Compositing

- Associated color: \( \tilde{F} = \alpha F \)
- Compositing with associated color:
  \[ \tilde{B}_{new} = (1 - \alpha) \tilde{B}_{old} + \tilde{F} \]
- and computing the new alpha:
  \[ \beta_{new} = (1 - \alpha) \beta_{old} + \alpha \]
- \( \beta \) is the \( \alpha \) of the background pixel.
Gamma Correction?

- Do you gamma-correct alpha? (Does alpha need a gamma correction?)
- Do you alpha-blend gamma? (Does an alpha blending change gamma?)
- Alpha is never gamma-corrected. Gamma-correction only applies to the “real” colors.
Textures

- Textures are pixmaps that are applied to faces.
- They can be “displayed” in all the different surface coefficients of the object, i.e. intensity or reflection coefficients.
- Texture pixmaps can either be stored beforehand or created by the program (procedural textures).
Textures

OpenGL needs to know which part of the texture belongs to which part of the face. Therefore, the vertices of the object are both specified in 3D worldspace and in texture coordinates. When rendering, OpenGL uses interpolated texture coordinates to find the “right” part of the texture.
Object and Texture Space

- A texture is a pixmap. It has a simple 2d coordinate system.
- A surface of an object has coordinates in 3d space.
- Question: how to find the right 2d coordinates for a pixel in 3d space. (This is yet another projection.)
Object and Texture Space

OpenGL knows several texture generation modes:

- **GL_OBJECT_LINEAR**: Texture coordinates are linear combinations of the vertex coordinates.
- **GL_EYE_LINEAR**: Texture coordinates are computed relative to the eye coordinates.
- **GL_SPHERE_MAP**
A Sphere Map
